EP 0 708 443 B1

Description

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0001] The present invention relates to a method and an apparatus for reproducing a recording medium. More specifically, the present invention is directed to a method and an apparatus for reproducing a recording medium with a memory used to temporarily store therein data read out from a recording medium.

2. Background of the Invention

[0002] Conventionally, such an apparatus whose vibration proof could be improved is realized by that a data rewritable magneto optical disk is employed as a recording medium, on which music data and the like can be recorded by a user, and data read out from the magneto optical disk is once stored into a memory.

[0003] In, for instance, a recording and/or reproducing apparatus capable of recording and/or reproducing a magneto optical disk, audio data read from the magneto optical disk is intermittently written into a buffer memory at a high transfer rate during the reproducing operation, whereas the audio data is continuously read out from the buffer memory at a low transfer rate to be demodulated as an audio (sound) reproduction signal. At this time, a certain data amount of audio data is being stored in the buffer memory. Accordingly, even when a track jump happens to occur due to applications of external vibrations to the recording and/or reproducing apparatus and thus the reading operation of the audio data from the magneto optical disk is temporarily interrupted, the audio data can be continuously read from the buffer memory. As a result, the reproduced sounds are outputted without any interruption.

[0004] During the recording operation, the input data is continuously, temporarily stored into the buffer memory at a low transfer rate, and then is intermittently read from this buffer memory at a high transfer rate to be supplied to the recording head, so that the read audio data is recorded on the disk.

[0005] In a recording track of a magneto optical disk functioning as the recording medium of the above-described recording and/or reproducing apparatus, as illustrated in FIG. 1, clusters CL (= 36 sectors) are continuously formed, each of which is constituted by a sub-data region of 4 sectors (1 sector = 2,352 bytes) and a main data region of 32 sectors. 1 cluster is used as a minimum unit during the recording operation. 1 cluster corresponds to tracks provided on 2 to 3 circumferences of the disk. It should be noted that an address is recorded every 1 sector. The sub-data region of 4 sectors is employed as sub-data and a linking area. TOC (Table of Contents) data, and audio data are recorded on the main data region of 32 sectors.

[0006] A sector is further subdivided into sound groups, and two sectors are subdivided into 11 sound groups. Within a sound group of 424 bytes, data is separated into an L-channel and a R-channel to be recorded. 1 sound group becomes such an audio data amount equal to 11.6 msec. 212 bytes for constituting either the L-channel region, or the R-channel region is called as a "sound frame".

[0007] When data is recorded and/or reproduced via the buffer memory, which has been recorded in such a format on the disk, the data is stored in a sector unit into the buffer memory. That is, the sector address is combined with the byte address (0 to 2351 bytes) within the sector to produce an access address, so that both the data write/read operations are performed.

[0008] In the above-described recording and/or reproducing apparatus, a fast-forward (FF) reproducing operation and a fast-return (FR) reproducing operation can be performed in addition to the normal reproducing operation. Such an apparatus and a corresponding method are known from EP 0597483 A. However, when the operation of said apparatus is switched between the normal reproducing operation and the fast-forward reproducing operation, and also between the normal reproducing operation and the fast-return reproducing operation, output sounds would be interrupted. Namely, a so-called "sound interruption" happens to occur. Thus, there is a problem that rhythmical operation feelings could not be obtained.

[0009] For example, during the fast-forward reproducing operation and the fast-return reproducing operation, the audio data are read from the disk for the fast-forward reproduction, or the fast-return reproduction, and then are stored into the buffer memory. These audio data are read from the buffer memory to be reproduced. The audio data read from the disk for the fast-forward reproduction, or the fast-return reproduction implies such temporally interrupted data produced by that for example, the data of several sectors have been read, and thereafter several tracks jump over, and then the data of several sectors are read. After the data have been once stored into the buffer memory, these data are sequentially read from the buffer memory, so that the sounds are outputted as the sound outputs corresponding to either the fast-forward reproduction, or the fast-return reproduction. However, when the operation is changed from the fast-forward reproduction, or the fast-return reproduction into the normal reproduction, the transfer operation of the data which have been stored in the buffer memory for the above purposes is interrupted, and then the data for the normal reproduction must be newly read from the disk to be stored into the buffer memory. The data for the normal reproduction implies such temporally continued data.

[0010] Accordingly, when the operation is switched from either the fast-forward reproduction, or the fast-return reproduction into the normal reproduction, the data reading operation from the buffer memory for the above

purpose is once interrupted. Thereafter, the data for the normal reproduction is read from the disk, and a certain data amount of data for the normal reproduction is stored in the buffer memory. Then, the newly stored data for the normal reproduction is read from the buffer memory, so that the reproduced sound output is commenced, during which the sounds are intermittently reproduced.

[0011] Also, when the operation is switched from the normal reproduction into either the fast-forward reproduction, or the fast-return reproduction, the transfer operation of the data for the normal reproduction from the buffer memory is once interrupted. Thereafter, the data for the fast-forward reproduction, or the fast-return reproduction is read from the disk, and a certain amount of data is stored into the buffer memory. Then, since the data for the fast-forward reproduction, or the fast-return reproduction is newly read from the buffer memory, either fast-forward reproduced sounds, or fast-return reproduced sounds can be newly outputted, during which the sounds are interrupted accordingly.

SUMMARY OF THE INVENTION

[0012] It is therefore an object of the present invention to provide a reproducing apparatus for a recording medium which resolves the above-mentioned problem.

[0013] It is another object of the present invention to provide a method for reproducing a recording medium which resolves the above-mentioned problem.

[0014] EP-A-0 597 483 is acknowledged in the preamble of apparatus claim 1 and method claim 9.

[0015] According to present invention, there is provided a reproducing apparatus for a recording medium including a reading unit, a memory and a controller. The reading unit is relatively moved with respect to the recording medium so as to read audio data recorded on the recording medium. The memory temporarily stores the audio data read from the recording medium. The controller controls to write the audio data into the memory and to read the audio data stored in the memory. The controller controls to write the audio data into the memory and to read the audio data therefrom in such a manner that a writing speed of the audio data read by the reading unit becomes higher than a reading speed of the audio data stored in the memory. When a high-speed reproducing operation condition is set, the controller causes a relatively transporting the head at a high speed with respect to the recording medium, whereby the highspeed reproducing operation process of the audio data is carried out, which is read out from the recording medium to be written into the memory, and address jump operations for reading the memory with respect to previously stored audio data for the normal reproducing operation before further audio data reading and address jump operations based on new audio data are performed, and during the reading and address jumping operations the reading means is independently carrying out track jumping operations, so that the data present

at the track to which the reading means jumps is read out from this track to be written into the memory as the new audio data.

[0016] According to the present invention, there is provided a method for reproducing a recording medium. Audio data is recorded together with address data on a recording medium. The audio data read from the recording medium by a reading unit is once stored into memory. The audio data stored in the memory is read, and the audio data is written/read into/from the memory in such a manner that a writing speed of the audio data read out from the recording medium is higher than a reading speed of the audio data stored in the memory. When a highspeed reproducing operation condition is set, the head is transported at a high speed with respect to the recording medium, whereby the highspeed reproducing operation process of the audio data is carried out, which is read out from the recording medium to be written into the memory, and address jump operations for reading the memory with respect to previously stored audio data for the normal reproducing operation before further audio data reading and address jump operations based on new audio data are performed, and during the reading and the jumping operations reading means is independently carrying out track jumping operations, so that the data present at the track to which the reading means jumps is read out from this track to be written into the memory as the new audio data.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017]

FIG. 1 pictorially shows a track format of a disk; FIG. 2 is a schematic block diagram for indicating an arrangement of a recording and/or reproducing apparatus; FIG. 3 pictorially represents a data sector of a disk; FIG. 4 is an explanatory diagram for showing a storage area of a buffer memory employed in the reproducing apparatus according to the embodiment; FIG. 5 is a flow chart for indicating a process operation of a sector counter provided at a disk drive side of a memory controller; FIG. 6 is a flow chart for explaining a process operation of a sector counter provided at an audio (sound) compression encoder/decoder of the memory controller; FIG. 7a and FIG. 7b are explanatory diagrams for describing operation of the buffer memory during the normal reproducing operation in the reproducing apparatus according to the embodiment; FIG. 8a and FIG. 8b are explanatory diagrams for describing operation of the buffer memory when the normal reproducing operation is changed to the fast-forward reproducing operation in the reproducing apparatus according to the embodiment; FIG. 9a and FIG. 9b are explanatory diagrams for

describing a first operation example of the buffer memory when the fast-forward reproducing operation is changed to the normal reproducing operation in the reproducing apparatus according to the embodiment;

FIG. 10a and FIG. 10b are explanatory diagrams for describing a second operation example of the buffer memory when the fast-forward reproducing operation is changed to the normal reproducing operation in the reproducing apparatus according to the embodiment;

FIG. 11a and FIG. 11b are explanatory diagrams for describing operation of the buffer memory when the normal reproducing operation is changed to the fast-return reproducing operation in the reproducing apparatus according to the embodiment;

FIG. 12a and FIG. 12b are explanatory diagrams for describing a third operation example of the buffer memory when the fast-return reproducing operation is changed to the normal reproducing operation in the reproducing apparatus according to the embodiment; and

FIG. 13a and FIG. 13b are explanatory diagrams for describing a fourth operation example of the buffer memory when the fast-return reproducing operation is changed to the normal reproducing operation in the reproducing apparatus according to the embodiment.

DETAILED DESCRIPTION OF THE INVENTION

[0018] Referring now to drawings, an apparatus for reproducing a recording medium, according to the present invention, will be described in detail. It should be understood that as the recording medium, such a magneto optical disk on which audio (sound) data is recorded is employed, whereas as the apparatus, such a recording and/or reproducing apparatus with employment of the magneto optical disk is employed for the sake of explanations in the below-mentioned embodiments.

[0019] A description will be made of the following items in the following sequence;

1. Arrangement of recording and/or reproducing apparatus.
2. Audio (sound) data sector.
3. Storage region of buffer memory.
4. Operation during normal reproducing operation.
5. Operation when normal reproducing operation is changed into fast-forward reproducing operation.
6. Operation when fast-forward reproducing operation is changed into normal reproducing operation.
7. Operation when normal reproducing operation is changed into fast-return reproducing operation.
8. Operation when fast-return reproducing operation is changed into normal reproducing operation.

1. Arrangement of Recording and/or Reproducing Apparatus

[0020] FIG. 2 is a schematic block diagram for showing a major portion of a recording and/or reproducing apparatus.

[0021] In FIG. 2, a magneto optical disk 1 on which, for instance, audio (sound) data is recorded is rotatably driven by a spindle motor 2. An optical head 3 irradiates an optical beam to the magneto optical disk 1 during the recording/reproducing operation. The optical head 3 irradiates to the disk 1, such a light beam having a high level used to heat a recording track up to the Curie temperature during the recording operation, whereas the optical head 3 irradiates to the disk 1, such a light beam having a relatively low level used to detect data from the reflection light from the disk 1 based on the magnetic Kerr effect during the reproducing operation.

[0022] To this end, the optical head 3 contains a laser diode functioning as a light source, an optical system constructed of a polarizing beam splitter and an objective lens 3a, and a detector for detecting reflection light. The objective lens 3a is held in such a way that this lens is displaceable by an actuator 4 along a disk radial direction as well as a direction along which this objective lens is positioned close to/apart from the disk.

[0023] A magnetic head 6a is located opposite to the optical head 3 by sandwiching the magneto optical disk 1, and this magnetic head 6a applies a vertical magnetic field modulated by the supplied data to the magneto optical disk 1. Both of the entire optical head 3 and the magnetic head 6a is transported by a feeding mechanism 5 along the radial direction of the disk 1.

[0024] During the reproducing operation, the information detected by the optical head 3 from the magneto optical disk 1 is supplied to an RF amplifier 7. The RF amplifier 7 extracts an RF signal, a tracking error signal, a focusing error signal, and absolute positional information by performing the calculation process of the supplied information. The absolute positional information is absolute positional information recorded on the magneto optical disk 1 as a pregroove (wobbling group). The RF signal outputted from the RF amplifier 7 is supplied to an encoder/decoder unit 8. Both of the tracking error signal and the focusing error signal, produced from the RF amplifier 7, are supplied to a servo circuit 9. The absolute positional information is supplied to an address decoder 10.

[0025] The servo circuit 9 produces various sorts of servo drive signals based on the tracking error signal and the focusing error signal supplied from the RF amplifier 7, and also a track jump instruction, an access instruction, and rotation speed detection information of the disk 1, which are derived from a system controller 11 arranged by a microcomputer. The servo circuit 9 controls the actuator 4 and the feeding mechanism 5 to perform a focus servo and a tracking servo. Based upon the rotation information from the disk 1, the servo circuit

9 controls the spindle motor 2 in the constant linear velocity (CLV) manner.

[0026] After the RF signal derived from the RF amplifier 7 is EFM-modulated and then decoded by way of the CIRC decoding process, the digital data outputted from the encoder/decoder unit 8 is once written into a buffer memory 13. The transfer data of the reproduced data in the signal system defined from the optical head 3 to the buffer memory 13, and also defined by the data readout operation from the magneto optical disk 1 by the optical head 3 is equal to 1.41 M bit/sec, and the reproduced data are intermittently performed.

[0027] The data written in the buffer memory 13 is read at such a timing when the transfer rate of the reproduced data becomes 0.3 M bit/sec, and then the read data is supplied into an encoder/decoder unit 14. The digital data supplied to the encoder/decoder unit 14 is processed in this encoder/decoder unit 14 by way of such a reproduction signal process as the decoding process for the audio compression process. The resultant digital data is D/A-converted into a corresponding analog signal by a D/A converter 15. The analog signal outputted from the D/A converter 15, i.e., the analog audio signal in this case, is supplied from an analog output terminal 16A to an external amplifier circuit unit so as to be amplified. The amplified signal is reproduced from a speaker and the like, for example, outputted as analog audio signals in an L-channel and a R-channel. Otherwise, the digital signal outputted from the encoder/decoder unit 14 is supplied to a digital outputted as a digital audio signal.

[0028] In this case, the data read/write operation to the buffer memory 13 is carried out by designating addresses by a memory controller 12 under read/write pointer control. As previously explained, the write pointer (write address) is incremented at the timing of 1.4 M bit/sec, whereas the read pointer (read address) is incremented at the timing of 0.3 M bit/sec. Due to a difference between the write bit rate and the read bit rate, a certain amount of data have been stored in the buffer memory 13. At a time when the data have been stored in the buffer memory 13 up to the full memory capacity of this buffer memory 13, the increment of the write pointer is stopped, and the data readout operation from the magneto optical disk 1 by the optical head 3 is also stopped. It should be noted that the increment of the read pointer is continuously executed, the reproduced audio (sound) output is not interrupted.

[0029] Thereafter, only the data readout operation from the buffer memory 13 is continued. Assuming now that the data stored amount of the buffer memory 13 becomes lower than a predetermined data amount, both of the data readout operation from the disk 1 by the optical head 3 and the increment of the write pointer are restarted, so that the data are again commenced to be stored into the buffer memory 13.

[0030] As described above, since the acoustic signal is outputted as the reproduction output via the buffer

memory 13, even when, for example, external disturbance is applied to the recording and/or reproducing apparatus to disturb the tracking servo control, the reproduced output is not interrupted. While the data remain in the buffer memory 13, for example, the scanning position by the optical head 3 may access to the correct tracking position before the tracking servo control is disturbed, and then the data readout operation from the disk 1 is restarted, so that the recording and/or reproducing operation can be continued without giving no adverse influence to the reproduced output. That is, the vibration proof function can be considerably increased.

[0031] The address information derived from the disk 1, and the subcode data used to the control operation, which are outputted from the address decoder 10, are supplied via the encoder/decoder unit 8 to the system controller 11 so as to be utilized to carry out various sorts of control operations.

[0032] Furthermore, also, a lock detecting signal of a PLL circuit for producing a bit clock of the recording/reproducing operation, and a monitor signal indicative of the dropout state of the frame sync signal of the reproduced data (R-channel and L-channel) are supplied to the system controller 11.

[0033] The system controller 11 outputs a laser control signal for controlling the operation of the laser diode of the optical head 3. In response to this laser control signal, the system controller 11 controls to turn ON/OFF the laser output of the laser diode, and also can switch an output whose output level is relatively low during the reproducing operation and another output whose output level is relatively high during the recording operation as the ON-control operation.

[0034] While the recording operation is executed to the magneto optical disk 1, the analog audio signal functioning as the recording signal supplied to the analog input terminal 17A is A/D-converted into a digital audio signal by an A/D converter 18. Thereafter, this digital audio signal is supplied to the encoder/decoder unit 14 to be processed by the audio compression encode process. Otherwise, the digital audio signal is supplied from the digital input terminal 17D, and this digital audio signal is furnished to the encoder/decoder unit 14 so as to be similarly processed by way of the audio compression encode process.

[0035] The digital data compressed by the encoder/decoder unit 14 is once written into the buffer memory 13 by the memory controller 12, and then is read from this buffer memory 13 at a preselected timing. Then, the read digital data is supplied to the encoder/decoder unit 8. After this digital data has been encode-processed by way of the CIRC encode and the EFM modulation, the resultant digital data is supplied to the magnetic head drive circuit 6.

[0036] In response to the recording data which has been encode-processed by the encoder/decoder 8, the magnetic head drive circuit 6 supplies a magnetic head drive signal to the magnetic head 6a. That is, either N-

vertical field, or S-vertical field is applied to the magneto optical disk 1 by the magnetic head 6a. At this time, the system controller 11 furnishes a laser control signal to the optical head 3 in order to output the optical beam having the recording level.

[0037] Reference numeral 19 indicates an operation input unit provided with user operation keys, and reference numeral 20 represents a display unit arranged by, for example, a liquid crystal display. In the operation input unit 19, there are provided a recording key, a reproducing key, a stop key, an X key, a fast-forward key, and a fast-return key for user manipulations.

[0038] When the reproducing operation for the disk 1 is carried out, the management information, i.e., P-TOC (prerecorded TOC) information and U-TOC (user TOC) information recorded on the disk 1 must be read out. In response to these management information, the system controller 11 may judge an address of an area where the data on the disk 1 should be recorded, and also an address of an area when the data should be reproduced. This management information is held in the buffer memory 13. Accordingly, as will be explained later, in the buffer memory 13, the above-described buffer area for storing the recording data/reproduced data, and the area for holding these management information are separately set.

[0039] The system controller 11 reads these management information by executing the reproducing operation of the area located at the innermost peripheral portion of the disk 1, where the management information has been recorded when the disk 1 is mounted on the recording and/or reproducing apparatus. Then, the read management information is stored into the buffer memory 13 under control of the system controller 11. The management information stored in the buffer memory 13 may be referred by the system controller 11 when the subsequent recording/reproducing operation for this disk 1 is carried out.

[0040] The U-TOC information may be edited and rewritten in accordance with the data recording/erasing operations. Every time the data recording/erasing operations are performed, the system controller 11 carries out this editing process to the U-TOC information stored in the buffer memory 13, and rewrites the U-TOC information at a preselected timing in response to the editing operation of the U-TOC information also as to the U-TOC area of the disk 1.

2. Audio Data Sector

[0041] As illustrated in FIG. 1, in the magneto optical disk employed in the recording and/or reproducing apparatus with such a structure, 32 sectors are present as a main data sector within 1 cluster. On the other hand, a format of a sector on which audio data is recorded is set as illustrated in FIG. 3.

[0042] In this sector (2,353 bytes), 12 bytes at a head portion are allocated as sync data. The subsequent 3

bytes are set to a cluster address and a sector address, and a further subsequent 1 byte is set to a mode, which thereby constitute a header.

[0043] Subsequent to this header, 4 bytes are set to a subheader, and bytes subsequent to the sub-header, namely 2,332 bytes defined from 21st byte to 2,352nd byte are set to a data area (Data 0 to Data 2331).

[0044] In this data area of 2,332 bytes, 11 units of sound frames constructed of 212 bytes are recorded, as illustrated in FIG. 1.

3. Storage Region of Buffer Memory

[0045] To store the data read from the disk 1 in the sector unit, in this embodiment, the buffer memory 13 owns such a storage area as shown in FIG. 4.

[0046] A storage capacity of the buffer memory 13 is set as 4 M bits, which contains 8 sectors for holding the TOC information.

[0047] Thus, 12 bytes (addresses 0000h to 000Ch) at a head portion are set as an empty area. The subsequent 18,944 bytes from addresses 000Ch to 4A0Bh are used to store the TOC information. In other words, 8 areas defined from an area 00 to an area 07 are separately used to hold the TOC sector. Each area is 2,368 bytes. Therefore, additional data of 16 bytes in addition to the data of 1 sector equal to 2,352 bytes can be stored.

[0048] An area defined from addresses 4A0Ch to 07FC4Bh is used to store either the data read from the disk 1, or the data to be recorded on the disk 1. That is, the area 08 to the area DC, each having 2,368 bytes are employed as the store/read operations of the audio data sector. Here, each of these areas is equal to 2,368 bytes, and therefore, additional data of 16 bytes can be stored in addition to data for 1 sector equal to 2,352 bytes.

[0049] It should be noted that an area defined from addresses 07FC4Ch to 07FFFFh is used as an empty area.

[0050] The audio data read from the disk 1 are sequentially written into the area 08 through the area DC in the sector unit while incrementing the write pointer as to the addresses 4A0Ch to 07FC4Bh used to store the audio data. The audio data writing operation is continued from the area DC, returning to the area 08.

4. Operation During Normal Reproducing Operation

[0051] In this embodiment, operations to the buffer memory 13 during the normal reproducing operation will now be explained.

[0052] FIG. 5 represents the normal reproducing operation, the fast-forward reproducing operation, and the fast-return reproducing operation as writing process operations of audio data read from the disk 1 into the buffer memory 13. FIG. 6 shows the normal reproducing operation, the fast-forward reproducing operation, and the fast-return reproducing operation as reading process

operations of audio data from the buffer memory 13.

[0053] The normal reproducing operation will be explained with reference to FIGs. 5, 6, 7(a) and 7(b).

[0054] In FIG. 5, a DSC (sector counter provided at disk drive side) corresponds to a write pointer when the data is fetched from the disk 1 into the buffer memory 13. In FIG. 6, an ASC (sector counter provided at audio compression encoder/decoder side) corresponds to a read pointer when the data is transferred from the buffer memory 13 to the audio compression encoder/decoder 14.

[0055] Both of the process operation shown in FIG. 5 to the buffer memory 13, and the process operation shown in FIG. 6 to this buffer memory 13 are independently carried out in the parallel manner by the memory controller 12.

[0056] As the process operation executed at the DCS side shown in FIG. 5, as an initializing operation, DSC, min DSC (effective limit position of DSC), max DSC (maximum position of DSC) are set to "0" or a specific position (F101). As the process operation executed at the ASC side indicated in FIG. 6, as an initialization operation, ASC is set to "0" or a specific position (F201).

[0057] During the reproducing operation, the process operation is advanced from the respective steps F102 and F202 to the process operation at the "PB" side.

[0058] As the DSC side, in response to a target cluster TGCL where a read starting position from the disk 1 is set, the system controller 11 controls the optical head 3 to read the audio data from the disk 1. The read audio data is stored into the buffer memory 13 in the sector unit at a high transfer rate in response to the increment operation of the DCC. At this time, the setting operations of min DSC and max DSC are corrected, if required (F103-F104-F105-F102-F103, ---).

[0059] On the other hand, on the ACS side, the audio data is read from the buffer memory 13 from an address indicated by the value of ASC in the sector unit at the low transfer rate. This reading operation is continued while incrementing the ASC (F203-F204→F202→F203, ---).

[0060] This condition is represented in FIG. 7a. FIGs. 7a and 7b schematically show such storage conditions that while incrementing the DSC, the audio data DTV for the normal reproducing operation is stored, and the stored audio data DTV for the normal reproducing operation is read out while incrementing the ASC. It should be understood that the audio data DTV for the normal reproducing operation implies such audio data which is read from the disk 1 by the above-explained normal reproducing operation and then is stored into the buffer memory 13. Accordingly, this definition is applied to the below-mentioned audio data DTV for the normal reproducing operation.

[0061] When the normal reproducing operation is further continuously performed, the storage condition shown in FIG. 7a is changed into the storage condition indicated in FIG. 7b.

[0062] The min DSC corresponding to the effective limit position of the DSC is first set to the DSC starting point, and thereafter is updated when the DSC is incremented in a ring form to rewrite the address of the min DSC. In other words, this min DSC indicates an address of audio data which becomes the temporally first data at each time instant as the audio data stored in the buffer memory 13.

[0063] During this normal reproducing operation, the audio data DTV read by the ASC is decoded by the audio compression encoder/decoder 14 to thereby be outputted as reproduced sounds.

5. Operation When Normal Reproducing Operation is changed into Fast-Forward Reproducing Operation

[0064] When the normal reproducing operation is changed into the fast-forward reproducing operation, the process operation performed on the DSC side is advanced from the step F102 to the FF side, whereas the process operation performed on the ASC side is advanced from the step F202 to the FF side. During the fast-forward reproducing operation, in response to the control signal supplied from the system controller 11, the optical head 3 is transported at a high speed along the radial direction of the disk 1, for instance, from the inner peripheral side to the outer peripheral side of this disk. Also, the track jump is repeatedly performed, so that the data present at the track to which the optical head 3 jumps is read out from this track. Thus, the read data is stored in the buffer memory 13. The switching operation from the normal reproducing operation into either the fast-forward reproducing operation, or the fast-return reproducing operation (will be discussed later) is carried out by manipulating the corresponding key of the operation input unit 19.

[0065] As indicated in FIG. 8a, in the case that when the normal reproducing operation is executed, the operation is switched into the fast-forward reproducing operation, the audio data DTV for the normal reproducing operation is read from the buffer memory 13 from the ASC value at this time on the ASC side (see FIG. 8b). The ASC increment is directly executed to read the audio data DTV in the sector unit. This implies the process operation defined by steps F205, F206, F208 to F205, ---, in the flow chart of FIG. 5.

[0066] After the audio data DTV for msectors have been read from the buffer memory 13, a jump value "J₁" is added to the ASC value, and then the audio data DTV for msectors are again read therefrom (F208→F209→F210).

[0067] In other words, as apparent from FIG. 8b, the audio data DTV which have been stored into the buffer memory 13 during the normal reproducing operation are read with respect to msectors, and also the address jump operation for the jump value J₁ is carried out. Then, by repeating both of the audio data reading operation

and the address jump operation, the sound reproduction is performed with employment of the audio data DTV for the normal reproducing operation, which are temporally continuous. As a consequence, just after the reproducing operation has been transferred to the fast-forward reproducing operation, the sounds reproduced by the fast-forward reproducing operation can be outputted without any sound interruption.

[0068] On the other hand, as indicated in FIG. 8b, in the case that the operation is transferred to the fast-forward reproducing operation at a halfway time instant of the previously stored audio data DTV, the audio data is continuously fetched from the disk 1 by employing the target cluster TGCL at this time on the DSC side. It should be noted all of the sectors of this target cluster TGCL are not fetched at this time, but the audio data for n sectors are read out from the disk 1 and then are stored into the buffer memory 13 while incrementing the DSC. As a consequence, as indicated as FFDT₁, audio data (n sectors) for the fast-forward reproducing operation, continued to the audio data DTV previously stored in the buffer memory 13, is stored (F106). It should be noted that the audio data for the fast-forward reproducing operation implies such data which has been read from the disk 1 while the optical head 3 is transported along the radial direction, namely the track jumping operation, and then has been stored into the memory 13.

[0069] Subsequently, in order to fetch the audio data for the fast-forward reproducing operation, the jump number JCL is added to the target cluster TGCL, and the next target cluster TGCL is set (F107). The next audio data FFDT₂ for the fast-forward reproducing operation is fetched by correcting the max DSC and the min DSC, if required (F108).

[0070] Subsequently, during the fast-forward reproducing operation, audio data FFDT₃, FFDT₄, ---, for the fast-forward reproducing operation are fetched into the buffer memory 13.

[0071] The audio data for n sectors among this audio data FFDTx for the fast-forward reproducing operation corresponds to temporally continued audio data, whereas the audio data FFDTx is not temporally continued to the audio data FFDT_{x+1}.

[0072] It should be noted that in the embodiment, n is set to 9 sectors and m is set to 5 sectors.

[0073] On the ASC side, during the fast-forward reproducing operation, the audio data for msectors is first read with respect to the audio data DTV for the normal reproducing operation, and the sound is outputted during the fast-forward reproducing operation by J₁ the address jump. Since the ASC is directly counted out, the audio data FFDT₁ for the fast-forward reproducing operation is read out. Here, since the respective audio data FFDTx for the fast-forward reproducing operation are not temporally continued, even when the ASC is incremented by every 1 sector to read the audio data, the sound during the fast-forward reproducing operation is obtained. However, since n sectors are continued, as-

suming now that this is 9 sectors, not so rhythmical sound for the fast-forward reproducing operation can be reproduced. Therefore, according to this embodiment, even when the audio data reading operation based upon the ASC is carried out for the audio data FFDTx for the fast-forward reproducing operation, the audio data for msectors is read and the address jump is carried out (F205 to F208). As a consequence, even when the audio data for 9 sectors is continuously fetched on the DSC side, for instance, only the audio data only for 5 sectors are reproduced to output the sound based on the fast-forward reproducing operation, so that the rhythmical sound can be outputted.

[0074] It should be noted that as to the address jump number, as a result of a judgement at a F209, after the reproduced audio data becomes the audio data FFDTx for the fast-forward reproducing operation, it is set to J₂ (namely, J₂<J₁) (F211).

6. Operation When Fast-Forward Reproducing Operation is changed into Normal Reproducing Operation

[0075] When the fast-forward reproducing operation is accomplished to be changed into the normal reproducing operation, the process operation executed on the ASC side is returned from the step F207 to the step F202 shown in FIG. 6, and process operations defined in steps F203 and F204 will now be carried out. That is, as the counter value of the ASC, the counter value obtained when this fast-forward reproducing operation is ended directly succeeds. It should be noted that the switching operation from either the fast-forward reproducing operation, or the fast-return reproducing operation (will be discussed later) into the normal reproducing operation is carried out by manipulating the keys of the operation input unit 19 in a similar manner to the above-described operation.

[0076] On the other hand, as the process operation executed on the DSC side, the process operation is advanced from the step F109 to a step F110 in FIG. 5. First, based on the present counter value of the ASC, the counter value of the DSC is again set. The process operation is transferred from the step F102 to process operations defined at steps F103, F104 and F105.

[0077] This transfer operation will now be explained based upon two examples indicated in FIGs. 9(a) and 9(b), and also FIGs. 10(a) and 10(b).

[0078] A first example is such a case that, as indicated in FIG. 9(a), after the fast-forward reproducing operation is commenced, the fast-return reproducing operation is complete at a time instant when the audio data DTV for the normal reproducing operation are still read on the ASC side.

[0079] At this time, as illustrated in FIG. 9(a), the normal reproducing operation is commenced from the counter value at this time on the ASC side. In other words, when the counter value of the ASC is increment-

ed by every 1 sector, the audio data is read from the buffer memory 13 for every preselected time period. As a consequence, the sound produced from the normal reproducing operation can be outputted without any sound interruption immediately after the process operation has been transferred to the normal reproducing operation.

[0080] On the other hand, even if the audio data FDT_4 for the fast-forward reproducing operation has been acquired into the buffer memory 13 on the DSC side, the present counter value of the DSC is not directly used, but is again set at the step F110 shown in FIG. 5.

[0081] That is, as shown in FIG. 9(b), a confirmation is made of such audio data stored at an address P_{1213} , which is read at 500 msec after the present counter value of the ASC.

[0082] Here, an address comparison is carried out between a sector at an address P_1 and a sector at an address (P_1-1) . If the sectors are not temporally continued, then the data in the sector to be stored at the address P_1 is stored. Namely, the data previously stored in the buffer memory 13, for example, the data continued to the audio data DTv stored on the disk 1 is read out from this disk 1 to be stored into the buffer memory 13. If the sector at the address P_1 is temporally continued to the sector at the address (P_1-1) , then a confirmation is made of the continuity of the sectors as to the subsequent addresses (P_1+1) , (P_1+2) , ---, and then a point where the continuity is interrupted is searched. The judgement as to whether or not the preceding sector (e.g., sector at address " P_1-1 ") is temporally continued to the succeeding sector (e.g., sector at address " P_1 ") is carried out by the system controller 12 to check the temporal continuity between the address data such as the sector address of the data stored in the preceding sector and the address data such as the sector address of the data stored in the succeeding sector. For instance, if the address data of the data stored in the preceding sector is very far from the address data of the data stored in the succeeding sector, then it may be judged that both of these address data are not temporally continued. To the contrary, if the sector of the address P_1 is temporally continued to the sector of the address (P_1-1) , then another confirmation is made of continuities as to the subsequent address (P_1+1) , (P_1+2) , ---, and a point where the continuities are interrupted is searched. On the other hand, when the audio data is written, or read in/from the buffer memory 13 in 1 cluster unit in the recording/reproducing apparatus of this embodiment, such a judgement may be made. That is, for example, if the cluster addresses of the address data after 500 msec are coincident with each other, then they are temporally continued. Otherwise, if the continuity is established in the lower-digit sector address of the cluster address, then they are temporally continued. The point where the continuities are interrupted as shown in FIG. 9(b), corresponds to a boundary between the audio data DTv for the normal reproducing operation and the audio data $FFDT_1$

for the fast-forward reproducing operation as to the stored data. As a result, as shown in FIG. 9(b), the DSC is set so as to correspond to the address P_2 , and the data readout operation from the disk 1 is restarted, so that the audio data for the normal reproducing operation are acquired into the buffer memory 13 so as to obtain the continuity.

[0083] It should be understood that the continuity would be interrupted as the sector data which have been stored at the addresses from the present ASC value after 500 msec. In this case, the sounds produced by the fast-forward reproducing operation would be outputted at this continuity interrupt portion. However, since this corresponds to a very short time period after the fast-forward reproducing operation is ended, there is no practical problem.

[0084] A second example implies such a case that as indicated in FIG. 10(a), after the fast-forward reproducing operation is started, the fast-forward reproducing operation is ended at a time instant when the audio data $FFDT_2$ for the fast-forward reproducing operation is read out on the ASC side.

[0085] At this time, as indicated in FIG. 10(a), on the ASC side, the normal reproducing operation is commenced at a time instant when the fast-forward reproducing operation is accomplished. That is, while the counter value of the ASC is incremented by every 1 sector, the audio data is read for a every predetermined time from the buffer memory 13. As a consequence, the sounds produced by the normal reproducing operation are outputted without any sound interrupt immediately after the operation is transferred to the normal reproducing operation. In particular, since as to the audio data $FFDTx$ for the fast-forward reproducing operation, the audio data for the relatively long "n" sectors and fetched, even when the audio data $FFDTx$ for the fast-forward reproducing operation is read out to some extent after the operation has been transferred to the normal reproducing operation, the audio data can be outputted as the sound output produced by the normal reproducing operation.

[0086] On the other hand, even if the audio data FDT_4 for the fast-forward reproducing operation has been acquired into the buffer memory 13 on the DSC side, the present counter value of the DSC is not directly used, but is again set at the step F110 shown in FIG. 5.

[0087] That is, as shown in FIG. 10(b), a confirmation is made of such audio data stored at an address P_1 , which is read at 500 msec after the present counter value of the ASC.

[0088] Here, an address comparison is carried out between a sector at an address P_3 and a sector at an address (P_3-1) . If the sectors are not temporally continued, then the data in the sector to be stored at the address P_3 is stored. Namely, the data previously stored in the buffer memory 13, for example, the data continued to the audio data $FFDT_3$ is read out from this disk 1 to be stored into the buffer memory 13. If the sector at the ad-

dress P_3 is temporally continued to the sector at the address (P_3-1), then a confirmation is made of the continuity of the sectors as to the subsequent addresses (P_3+1), (P_3+2), ---, and then a point where the continuity is interrupted is searched. The method for searching the point where the continuity is interrupted may be performed by employing the method as explained in, for example, FIGs. 9(a) and 9(b). The point where the continuities are interrupted as shown in FIG. 10(b), corresponds to a boundary between the audio data FFDT₃ and the audio data FFDT₄ for the fast-forward reproducing operation as to the stored data. As a result, as shown in FIG. 10(b), the DSC is set so as to correspond to the address P_4 , and the data readout operation from the disk 1 is restarted, so that the audio data DTV for the normal reproducing operation are acquired into the buffer memory 13 so as to obtain the continuity from the audio data FFDT₄ for the fast-forward reproducing operation.

[0089] It should be understood that the continuity would be interrupted at the boundary between the data FFDT₂ and the data FFDT₃ for the fast-forward reproducing operation in this case as the sector data which have been stored at the addresses from the present ASC value after 500 msec. In this case, the sounds produced by the fast-forward reproducing operation would be outputted at this continuity interrupt portion. However, since this corresponds to a very short time period after the fast-forward reproducing operation is ended, there is no practical problem.

7. Operation When Normal Reproducing Operation is changed into Fast-Return Reproducing Operation

[0090] When the normal reproducing operation is changed into the fast-return reproducing operation, the process operation executed on the DSC side is advanced from the step F102 to the FR side, and the process operation executed on the ASC side is advanced from the step F202 to the FR side. During the fast-forward reproducing operation, the optical head 3 is transported at a high speed along the radial direction of the disk 1, for instance, along such a direction from the outer peripheral portion of the disk to the inner peripheral portion thereof in response to the control signal derived from the system controller 11. Also, the track jump is repeated, so that the data stored in the track to which the optical head 3 jumps is read out. Thus, the read data is stored in the buffer memory 13.

[0091] As indicated in FIG. 11a in the case that when the normal reproducing operation is executed, the operation is switched into the fast-return reproducing operation, the audio data DTV for the normal reproducing operation is read from the buffer memory 13 from the ASC value at this time on the ASC side (see FIG. 11b). The ASC increment is directly executed to read the audio data DTV in the sector unit. This implies the process operation defined by steps F212, F213, F215 to F212,

---, in the flow chart of FIG. 5.

[0092] After the audio data DTV for msectors have been read from the buffer memory 13 along the reverse direction, a jump value " J_1 " is subtracted from the ASC value, and then the audio data DTV for msectors are again read therefrom along the reverse direction (F215-F216-F217).

[0093] In other words, as apparent from FIG. 11c, the audio data DTV which have been stored into the buffer memory 13 as the data for the normal reproducing operation are read with respect to msectors along the reverse direction, and also the read address jump operation for the jump value J_1 is carried out along the reverse direction. Then, by repeating both of the audio data reading operation and the address jump operation, the sound reproduction is performed with employment of the audio data DTV for the normal reproducing operation, which are temporally continuous. As a consequence, just after the reproducing operation has been transferred to the fast-forward reproducing operation, the sounds reproduced by the fast-forward reproducing operation can be outputted without any sound interruption.

[0094] On the other hand, as indicated in FIG. 11b, in the case that the operation is transferred to the fast-return reproducing operation at a halfway time instant of the previously stored audio data DTV, the target cluster TGCL is set to a predetermined position along the fast-return reproducing direction as the read position from the disk 1. This implies that such a cluster is set which owns the audio data temporally before the audio data stored in the min DSC at this time (F111).

[0095] Next, the counter value of the DSC is set as a value of min DSC-(n). In other words, it is set as a value corresponding to the address P_5 of FIG. 11a. In response to the target cluster TGCL, the audio data read out from the disk 1 is fetched into the buffer memory 13. It should be noted that all of the sectors of this target cluster TGCL are not fetched at this time, but the audio data for n sectors are read out from the disk 1 and then are stored into the buffer memory 13 while incrementing the DSC. As a consequence, as indicated as FFDT₁, audio data (n sectors) for the fast-return reproducing operation is stored (F113). It should be noted that the audio data for the fast-return reproducing operation implies such data which has been read from the disk 1 while the optical head 3 is transported along the radial direction, for example, a direction opposite to that of the fast-forward reproducing operation, and then has been stored into the memory 13.

[0096] Subsequently, in order to fetch the audio data for the fast-return reproducing operation, the jump number JCL is subtracted from the target cluster TGCL, and the next target cluster TGCL is set (F114). The max DSC and the min DSC are corrected, if required (F115). At this time, the min DSC is again set to the address P_5 as indicated as min DSC #1.

[0097] Then, the process operation is returned to the

step F112 at which the DSC is again set in order to fetch the next audio data $FFDT_2$ for the fast-return reproducing operation. In other words, the DSC is set to a point P_6 located before the min DSC #1 at this time by n sectors.

[0098] Thereafter, during the fast-return reproducing operation, the audio data $FRDT_2$, $TRDT_3$, $TRDT_4$, ---, for the fast-return reproducing operation are sequentially, and temporally returned, and are fetched for every n sectors. Also in the buffer memory 13, these data are acquired at the address positions which are temporally returned. It should be noted as to the n sectors within the respective audio data $TRDT_x$ for the fast-return reproducing operations, these data are stored while the DSC is incremented. These audio data are continued in the same temporal order as that of the normal reproducing operation.

[0099] The audio data for n sectors among this audio data $FFDT_x$ for the fast-return reproducing operation corresponds to temporally continued audio data, whereas the audio data $FRDT_x$ is not temporally continued to the audio data $FRDT_{x+1}$.

[0100] On the ASC side, during the fast-return reproducing operation, the audio data for m sectors is first read with respect to the audio data DT_v for the normal reproducing operation, and the sound is outputted during the fast-return reproducing operation by the J_1 address jump. Since the ASC is directly counted out along the return direction, the audio data $FRDT_1$ for the fast-return reproducing operation is read out. Here, since the respective audio data $FRDT_x$ for the fast-return reproducing operation are not temporally continued, even when the ASC is incremented by every 1 sector to read the audio data, the sound during the fast-return reproducing operation is obtained. However, according to this embodiment, even when the audio data reading operation based upon the ASC is carried out for the audio data $FRDT_x$ for the fast-return reproducing operation, the audio data for m sectors is read and the address jump is carried out (F212 to F215). It should be noted that as to the address jump number along the return direction, as a result of a judgement at a step F216, after the reproduced audio data becomes the audio data $FRDT_x$ for the fast-return reproducing operation, it is set to J_2 (namely, $J_2 < J_1$) (F218).

8. Operation When Fast-Return Reproducing Operation is changed into Normal Reproducing Operation

[0101] When the fast-return reproducing operation is accomplished to be changed into the normal reproducing operation, the process operation executed on the ASC side is returned from the step F214 to the step F202 shown in FIG. 6, and process operations defined in steps F203 and F204 will now be carried out. That is, as the counter value of the ASC, the counter value obtained when this fast-return reproducing operation is ended is

employed and the increment thereof is directly restarted, so that the data reading operation is commenced for every 1 sector.

[0102] On the other hand, as the process operation executed on the DSC side, the process operation is advanced from the step F116 to a step F110 in FIG. 5. First, based on the present counter value of the ASC, the counter value of the DSC is again set. The process operation is transferred from the step F102 to process operations defined at steps F103, F104 and F105.

[0103] This transfer operation will now be explained based upon two examples indicated in FIGs. 12(a) and 12(b), and also FIGs. 13(a) and 13(b).

[0104] A third example is such a case that, as indicated in FIG. 12(a) after the fast-return reproducing operation is commenced, the fast-return reproducing operation is complete at a time instant when the audio data DT_v for the normal reproducing operation are still read on the ASC side.

[0105] At this time, as illustrated in FIG. 12(b), the normal reproducing operation is commenced from the counter value at this time on the ASC side. In other words, when the counter value of the ASC is incremented by every 1 sector, the audio data is read from the buffer memory 13 for every preselected time period. As a consequence, the sound produced from the normal reproducing operation can be outputted without any sound interruption immediately after the process operation has been transferred to the normal reproducing operation. In other words, the data is read from the buffer memory 13 in a direction along which the time has elapsed from the temporally returned fast-return reproducing operation, and then the read data is reproduced.

[0106] On the other hand, the counter value used to acquire the audio data $FRDT$ for the fast-forward reproducing operation is not directly used on the DSC side, but is again set at the step F110 shown in FIG. 5.

[0107] That is, as shown in FIG. 12(b), a confirmation is made of such audio data stored at an address P_7 , which is read at 500 msec after the present counter value of the ASC.

[0108] Here, an address comparison is carried out between a sector at an address P_7 and a sector at an address (P_7-1) . If the sectors are not temporally continued, then the data in the sector to be stored at the address P_7 is stored. Namely, the data previously stored in the buffer memory 13, for example, the data continued to the audio data DT_v stored on the disk 1 is read out from this disk 1 to be stored into the buffer memory 13. If the sector at the address P_7 is temporally continued to the sector at the address (P_7+1) , (P_7+2) , ---, and then a point where the continuity is interrupted is searched. The method for searching the point where the continuity is interrupted is carried out by way of the methods, as previously explained with reference to FIGs. 9(a) and 9(b). In the example indicated in FIG. 12(b), the point where the continuity is interrupted corresponds to such a point where the stored data DT_v for the normal repro-

ducing operation is ended. As a result, as shown in FIG. 12(b), the DSC is set so as to correspond to the address P_8 , and the data readout operation from the disk 1 is restarted, so that the audio data for the normal reproducing operation are acquired into the buffer memory 13 so as to obtain the continuity.

[0109] A fourth example implies such a case that as indicated in FIG. 13(a), after the fast-return reproducing operation is started, the fast-forward reproducing operation is ended at a time instant when the audio data $FRDT_3$ for the fast-forward reproducing operation is read out on the ASC side.

[0110] At this time, as indicated in FIG. 13(b), on the ASC side, the normal reproducing operation is commenced at a time instant when the fast-forward reproducing operation is accomplished. That is, while the counter value of the ASC is incremented by every 1 sector, the audio data is read for every predetermined time from the buffer memory 13. Since the respective sectors in the audio data $FRDT_3$ for the fast-return reproducing operation have been stored while the DSC is incremented (along the normal reproducing direction), the process operation is transferred to the normal reproducing operation. Thus, immediately after the ASC is changed from the decrement operation into the increment operation, the sound produced during the normal reproducing operation is outputted without any sound interruption. In particular, since as to the audio data $FRDT_x$ for the fast-return reproducing operation, the audio data for the relatively long "n" sectors are fetched, even when the audio data $FRDT_x$ for the fast-return reproducing operation is read out to some extent after the operation has been transferred to the normal reproducing operation, the audio data can be outputted as the sound output produced by the normal reproducing operation.

[0111] On the other hand, the counter value used to acquire the audio data $FFDT_x$ for the fast-return reproducing operation is not utilized on the DSC side, but is again set at the step F110 of FIG. 5.

[0112] That is, as shown in FIG. 13(b), a confirmation is made of such audio data stored at an address P_9 , which is read at 500 msec after the present counter value of the ASC.

[0113] Here, an address comparison is carried out between a sector at an address P_9 and a sector at an address (P_9-1) . If the sectors are not temporally continued, then the data in the sector to be stored at the address P_9 is stored. Namely, the data on the disk 1, which is temporally continued to the data of the sector at the address (P_8-1) stored in the buffer memory 13 is read out, and then the read data is stored into the buffer memory 13. If the sector at the address P_9 is temporally continued to the sector at the address (P_9-1) , then a confirmation is made of the continuity of the sectors as to the sectors as to the subsequent addresses (P_9+1) , (P_9+2) , ---, and then a point where the continuity is interrupted is searched. The method for searching the point where the continuity is interrupted is carried out by employing

the methods as explained in FIGs. 9(a) and 9(b).

[0114] The point where the continuities are interrupted as shown in FIG. 13(b), corresponds to an address P_{10} of a boundary between the audio data $FRDT_1$ for the fast-forward reproducing operation in FIG. 13(a).

[0115] Accordingly, the counter value of the DSC is set to a value corresponding to the address P_{10} , and the data writing operation from the disk 1 is restarted from this state. As represented in FIG. 13(b), the audio data is read out from the disk 1 in order to obtain the continuity from the data $FRDT_2$ for the fast-return reproducing operation. Then, the read audio data is acquired into the buffer memory 13 as the data DTV for the normal reproducing operation.

[0116] It should be understood that the continuity would be interrupted as the sector data which have been stored at the addresses from the present ASC value after 500 msec. In this case, the continuity is interrupted at the boundary between the audio data $FRDT_3$ and $FRDT_2$ for the fast-return reproducing operation, and such a sound produced during the fast-return reproducing operation is outputted at this boundary portion. However, since this corresponds to a very short time period after the fast-return reproducing operation is ended, there is no practical problem.

[0117] As described above, in accordance with the present embodiment, when the normal reproducing operation is transferred to the highspeed reproducing operation such as the fast-forward reproducing operation, or the fast-return reproducing operation, the sound produced by the highspeed reproducing operation is first outputted by employing the audio data DTV for the normal reproducing operation, which has been stored in the buffer memory 13. As a consequence, no sound interruption occurs during the transfer operation between the reproducing operations, and smooth operation feelings can be realized.

[0118] When the reproducing operation is transferred from the highspeed reproducing operation such as the fast-forward reproducing operation or the fast-return reproducing operation into the normal reproducing operation, either the audio data DTV for the normal reproducing operation, or the audio data ($FFDT_x$, $FRDT_x$) for the fast-forward/fast-return reproducing operations, which has been stored in the buffer memory 13 at this time, is employed to reproduce the sounds. Accordingly, no sound interruption occurs during the transition of the reproducing operations, and smooth operation feelings can be realized.

[0119] It should be noted that while the various embodiments have been described, the reproducing apparatus according to the present invention is not limited to the above-described arrangements of these embodiments, and also the actual processing sequences are not restricted to those shown in FIGs. 5 and 6, but may be changed. Although the reproducing apparatus using the magneto optical disk as the recording medium has been described in the above-described embodiment,

the present invention may be similarly applied to such a reproducing apparatus with using a tape-shaped magnetic medium such as a magnetic tape.

Claims

1. A reproducing apparatus for a recording medium, comprising:

reading means (3, 6) relatively moved with respect to a recording medium (1), for reading audio data recorded on the recording medium (1); memory means (13) for temporarily storing therein the audio data read from the recording medium (1) by said reading means (3, 6); and control means (12) for controlling a writing operation (DSC) of said audio data into said memory means (13) and a reading operation (ASC) of said audio data (DTV) stored in said memory means (13), wherein said control means (12) controls to write the audio data into said memory means (13) and to read the audio data therefrom in such a manner that a writing speed of the audio data read by said reading means (3, 6) becomes higher than a reading speed of the audio data stored in said memory means (13) wherein when a highspeed reproducing operation condition (FF, FR) is set, said control means (12) causes relatively transporting of said reading means (3, 6) at a high speed with respect to the recording medium (1), whereby the highspeed reproducing operation process of said audio data is carried out, which is read out from the recording medium (1) to be written into said memory means,

characterised in that,

when a highspeed reproducing operation condition (FF, FR) is set, said control means (12) further causes address jump operations (J1) for reading (ASC) the memory (13) with respect to previously stored audio data (DTV) for the normal reproducing operation (PB) before further audio data reading and address jump operations (J2) based on new audio data (FFDT, FRDT) are performed, and during said reading and address jump operations (J1, J2) the reading means (3, 6) is independently carrying out track jumping operations, so that the data present at the track to which the reading means (3, 6) jumps is read out from this track to be written into said memory (13) as said new audio data (FFDT, FRDT).

2. A reproducing apparatus for a recording medium as claimed in claim 1 wherein:

when said highspeed reproducing operation condition is set, said control means (12) causes

reading out a preselected amount of said audio data stored in said memory means (13) therefrom in a discontinuous manner.

3. A reproducing apparatus for a recording medium as claimed in claim 2 wherein:

when said highspeed reproducing operation condition is set, said control means (12) causes relatively transporting said reading means (3) with respect to the recording medium (1) in such a manner that said audio data is read from the recording medium, whose data amount is larger than such a data amount of the audio data when said audio data stored in said memory means is read out therefrom.

4. A reproducing apparatus for a recording medium as claimed in claim 3 wherein:

when said highspeed reproducing operation condition is set, said control means (12) causes relatively transporting said reading means at a high speed with respect to the recording medium from such an address which is continued to the audio data previously stored in said memory means (13) and is temporally located downstream, whereby the audio data read from the recording means is written into said memory means.

5. A reproducing apparatus for a recording medium as claimed in any one of the preceding claims wherein:

when there is switched from said highspeed reproducing operation condition is switched into a normal reproducing operation condition, said control means causes continuously reading the audio data stored in said memory means (12) at the time instant at which said highspeed reproducing operation condition is switched into the normal reproducing operation condition.

6. A reproducing apparatus for a recording medium as claimed in claim 5 wherein:

after the operation condition has been brought into said normal reproducing operation condition, said control means (12) causes writing the audio data read from said recording medium (1) into said memory means (13) from a head position of the audio data having an address different from an address of the audio data read from said memory means (13) at the time instant at which said highspeed reproducing operation condition is switched into said normal reproducing operation condition.

7. A reproducing apparatus for a recording medium as claimed in claim 6 wherein:

said control means (12) judges whether or not the address of the audio data read from said memory means (13) at the time instant at which said highspeed reproducing operation condition is changed into the normal reproducing operation condition is continued to an address of the audio data separated by a predetermined distance from said audio data read from the memory means at said changing time instant, whereby a head position of the audio data having said different address is determined.

8. A reproducing apparatus for a recording medium as claimed in claim 6 wherein:

said control means (12) compares the address of the audio data read from said memory means (13) at the time instant at which said highspeed reproducing operation condition is changed into said normal reproducing operation condition with an address of the audio data separated by a predetermined distance from the audio data read from said memory means (13) at said changing time instant; and when a comparison result implies that the address of said read audio data is not continued the address of said audio data separated by said predetermined distance therefrom, said control means (12) writes the audio data read from said reading means from said separated audio data at a head position.

9. A method for reproducing a recording medium (1) in which audio data is recorded together with address data on a recording medium (1); the audio data read from said recording medium by reading means (3, 6) is once stored into memory means (13); the audio data stored in the memory means (13) is read; and the audio data is written/read into/from the memory means (13) in such a manner that a writing speed of the audio data read out from the recording medium (1) is higher than a reading speed of the audio data stored in the memory means (13); wherein when a highspeed reproducing operation condition is set, said reading means (3, 6) is relatively transported at a high speed with respect to the recording medium (1), whereby the highspeed reproducing operation process of said audio data is carried out, which is read out from the recording medium (1) to be written into said memory means,

characterised in that

wherein when a highspeed reproducing operation condition is set, said reproducing method further executes address jump operations (J1) for reading

(ASC) the memory (13) with respect to previously stored audio data (DTv) for the normal reproducing operation (PB) before further audio data reading and address jump operations (J2) based on new audio data (FFDT, FRDT) are performed, and during said reading and address jumping operations (J1, J2) the reading means (3, 6) is independently carrying out track jumping operations, so that the data present at the track to which the reading means (3, 6) jumps is read out from this track to be written into said memory (13) as said new audio data (FFDT, FRDT).

10. A reproducing method as claimed in claim 9 wherein:

when said highspeed reproducing operation condition is set, a preselected amount of said audio data stored in said memory means (13) is read therefrom in a discontinuous manner.

11. A reproducing method as claimed in claim 10 wherein:

when said highspeed reproducing operation condition is set, said reading means (3) is relatively transported with respect to the recording medium (1) in such a manner that said audio data is read from the recording medium (1), whose data amount is larger than such a data amount of the audio data when said audio data stored in said memory means (13) is read out therefrom.

12. A reproducing method as claimed in claim 11 wherein:

when said highspeed reproducing operation condition is set, said reading means (3) is relatively transported at a high speed with respect to the recording medium (1) from such an address which is continued to the audio data previously stored in said memory means (13) and is temporally located at a down stream, whereby the audio data read from the recording means is written into said memory means (13).

13. A reproducing method as claimed in any one of claims 9 to 12 wherein:

when said highspeed reproducing operation condition is switched into a normal reproducing operation condition, the audio data stored in said memory means (13) at a time instant when said highspeed reproducing operation condition is switched into the normal reproducing operation condition, is continuously read.

14. A reproducing method as claimed in claim 13 wherein:

after the operation condition has been brought into said normal reproducing operation condition, the audio data read from said recording medium (1) is written into said memory means (13) from a head position of the audio data having an address different from an address of the audio data read from said memory means (13) at the time instant when said highspeed reproducing operation condition is switched into said normal reproducing operation condition.

15. A reproducing method as claimed in any one of claims 9 to 14 wherein:

a judgement is made as to whether or not the address of the audio data read from said memory means (13) at the time instant when said highspeed reproducing operation condition is changed into the normal reproducing operation condition is continued to an address of the audio data separated by a predetermined distance from said audio data read from the memory means (13) at said changing time instant, whereby a head position of the audio data having said different address is determined.

Patentansprüche

1. Wiedergabevorrichtung für ein Aufzeichnungsmedium, mit:

Einer relativ zu einem Aufzeichnungsmedium (1) bewegten Leseeinrichtung (3, 6) zum Lesen von auf dem Aufzeichnungsmedium (1) aufgezeichneten Audiodaten, einer Speichereinrichtung (13) zum zeitweiligen Speichern der durch die Leseeinrichtung (3, 6) vom Aufzeichnungsmedium gelesenen Audiodaten, und einer Steuerungseinrichtung (12) zur Steuerung einer Schreiboperation (DSC) der Audiodaten in die Speichereinrichtung (13) und einer Leseoperation (ASC) der in der Speichereinrichtung (13) gespeicherten Audiodaten (DTv), wobei die Steuerungseinrichtung (12) zum Schreiben der Audiodaten in die Speichereinrichtung (13) und daraus Lesen der Audiodaten derart steuert, dass eine Schreibgeschwindigkeit der von der Leseeinrichtung (3, 6) gelesenen Audiodaten höher als eine Lese- geschwindigkeit der in der Speichereinrichtung (13) gespeicherten Audiodaten wird, wobei beim Eingestellt sein eines Hochgeschwindigkeits-Wiedergabeoperationszustandes (FF, FR) die Steuerungseinrichtung (12) einen relativen Transport der Leseeinrichtung (3, 6) in Bezug auf das Aufzeichnungsmedium (1) mit einer hohen Geschwindigkeit bewirkt, wodurch der Hochgeschwindigkeits-Wiedergabeoperationsprozess der aus dem Aufzeichnungsmedium (1) zum Schreiben in die Speichereinrichtung gelesenen Audiodaten ausgeführt wird,

FR) die Steuerungseinrichtung (12) einen relativen Transport der Leseeinrichtung (3, 6) in Bezug auf das Aufzeichnungsmedium (1) mit einer hohen Geschwindigkeit bewirkt, wodurch der Hochgeschwindigkeits-Wiedergabeoperationsprozess der aus dem Aufzeichnungsmedium (1) zum Schreiben in die Speichereinrichtung gelesenen Audiodaten ausgeführt wird,

dadurch gekennzeichnet, dass

bei einem Eingestellt sein des Hochgeschwindigkeits-Wiedergabeoperationszustandes (FF, FR) die Steuerungseinrichtung (12) außerdem Adressensprungoperationen (J1) zum Lesen (ASC) des Speichers (13) in Bezug auf vorher für die normale Wiedergabeoperation (PB) gespeicherte Audiodaten (DTv) bewirkt, bevor während der Lese- und Adressensprungoperationen (J1) weitere Audiodatenlese- und Adressensprungoperationen (J2) auf der Basis neuer Audiodaten (FFDT, FRDT) ausgeführt werden, und die Leseeinrichtung (3, 6) unabhängig Spursprungoperationen so ausführt, dass die bei der Spur vorhandenen Daten, zu welcher die Leseeinrichtung (3, 6) springt, aus dieser Spur ausgelesen werden, um in den Speicher (13) als die neuen Audiodaten (FFDT, FRDT) geschrieben zu werden.

2. Wiedergabevorrichtung für ein Aufzeichnungsmedium nach Anspruch 1, wobei

beim Eingestellt sein des Hochgeschwindigkeits-Wiedergabeoperationszustandes die Steuerungseinrichtung (12) ein Auslesen einer vorgewählten Menge der in der Speichereinrichtung (13) gespeicherten Audiodaten aus derselben auf diskontinuierliche Weise bewirkt.

3. Wiedergabevorrichtung für ein Aufzeichnungsmedium nach Anspruch 2, wobei

beim Eingestellt sein des Hochgeschwindigkeits-Wiedergabeoperationszustandes die Steuerungseinrichtung (12) einen relativen Transport der Leseeinrichtung (3) in Bezug auf das Aufzeichnungsmedium (1) derart bewirkt, dass die Audiodaten aus dem Aufzeichnungsmedium, dessen Datenmenge größer als eine solche Datenmenge der Audiodaten ist, gelesen werden, wenn die in der Speichereinrichtung gespeicherten Audiodaten aus derselben gelesen werden.

4. Wiedergabevorrichtung für ein Aufzeichnungsmedium nach Anspruch 3, wobei

- beim Eingestellt sein des Hochgeschwindigkeits-Wiedergabeoperationszustandes die Steuerungseinrichtung (12) einen relativen Transport der Leseeinrichtung in Bezug auf das Aufzeichnungsmedium mit hoher Geschwindigkeit von einer Adresse derart, dass sie an den vorher in der Speichereinrichtung (13) gespeicherten Audiodaten fortgesetzt und zeitlich stromabwärts angeordnet ist, bewirkt, wobei die aus der Aufzeichnungseinrichtung gelesenen Audiodaten in die Speichereinrichtung geschrieben werden.
5. Wiedergabevorrichtung für ein Aufzeichnungsmedium nach einem der vorhergehenden Ansprüche, wobei
- beim Schalten vom Hochgeschwindigkeits-Wiedergabeoperationszustand in einen normalen Wiedergabeoperationszustand die Steuerungseinrichtung ein kontinuierliches Lesen der in der Speichereinrichtung (13) gespeicherten Audiodaten zu dem Zeitpunkt bewirkt, bei dem der Hochgeschwindigkeits-Wiedergabeoperationszustand in den normalen Wiedergabeoperationszustand geschaltet wird.
6. Wiedergabevorrichtung für ein Aufzeichnungsmedium nach Anspruch 5, wobei
- nach dem Bringen des Operationszustandes in den normalen Wiedergabeoperationszustand die Steuerungseinrichtung (12) ein Schreiben der aus dem Aufzeichnungsmedium (1) gelesenen Audiodaten in die Speichereinrichtung (13) von einer Kopfposition der eine von einer Adresse der aus der Speichereinrichtung (13) gelesenen Audiodaten verschiedene andere Adresse aufweisenden Audiodaten zu dem Zeitpunkt bewirkt, bei dem der Hochgeschwindigkeits-Wiedergabeoperationszustand in den normalen Wiedergabeoperationszustand geschaltet wird.
7. Wiedergabevorrichtung für ein Aufzeichnungsmedium nach Anspruch 6, wobei
- die Steuerungseinrichtung (12) feststellt, ob die Adresse der zu dem Zeitpunkt aus der Speichereinrichtung (13) gelesenen Audiodaten, bei dem der Hochgeschwindigkeits-Wiedergabeoperationszustand in den normalen Wiedergabeoperationszustand wechselt, sich bei einem anderen Abstand, die um einen vorbestimmten Abstand von den beim Wechselzeitpunkt aus der Speichereinrichtung gelesenen Audiodaten getrennt ist, fortgesetzt ist oder nicht, wobei eine Kopfposition der die andere
- Adresse aufweisenden Audiodaten bestimmt wird.
8. Wiedergabevorrichtung für ein Aufzeichnungsmedium nach Anspruch 6, wobei
- die Steuerungseinrichtung (12) die Adresse der zu dem Zeitpunkt aus der Speichereinrichtung (13) gelesenen Audiodaten, bei dem der Hochgeschwindigkeits-Wiedergabeoperationszustand in den normalen Wiedergabeoperationszustand wechselt, mit einer Adresse der von den zum Wechselzeitpunkt aus der Speichereinrichtung (13) gelesenen Audiodaten durch einen vorbestimmten Abstand getrennten Audiodaten vergleicht, und, wenn ein Vergleichsergebnis impliziert, dass sich die Adresse der gelesenen Audiodaten nicht an der Adresse der durch den vorbestimmten Abstand davon getrennten Audiodaten fortsetzt, die Steuerungseinrichtung (12) die aus der Leseeinrichtung von den getrennten Audiodaten gelesenen Audiodaten an einer Kopfposition schreibt.
9. Verfahren zur Wiedergabe eines Aufzeichnungsmediums (1), bei welchem Verfahren Audiodaten zusammen mit Adressendaten auf einem Aufzeichnungsmediums (1) aufgezeichnet werden, die von einer Leseeinrichtung (3, 6) vom Aufzeichnungsmedium gelesenen Audiodaten einmal in einer Speichereinrichtung (13) gespeichert werden, die in der Speichereinrichtung (13) gespeicherten Audiodaten gelesen werden, und die Audiodaten in die/aus der Speichereinrichtung (13) geschrieben/gelesen werden, derart, dass eine Schreibgeschwindigkeit der aus dem Aufzeichnungsmedium (1) gelesenen Audiodaten höher als eine Lesegeschwindigkeit der in der Speichereinrichtung (13) gespeicherten Audiodaten ist, wobei beim Eingestellt sein eines Hochgeschwindigkeits-Wiedergabeoperationszustandes die Leseeinrichtung (3, 6) in Bezug auf das Aufzeichnungsmedium (1) mit einer hohen Geschwindigkeit relativ transportiert wird, wodurch der Hochgeschwindigkeits-Wiedergabeoperationsprozess der aus dem Aufzeichnungsmedium (1) zum Schreiben in die Speichereinrichtung gelesenen Audiodaten ausgeführt wird, **dadurch gekennzeichnet, dass**
- bei einem Eingestellt sein eines Hochgeschwindigkeits-Wiedergabeoperationszustandes das Wiedergabeverfahren Adressensprungoperationen (J1) zum Lesen (ASC) des Speichers (13) in Bezug auf vorher für die normale Wiedergabeoperation (PB) gespeicherte Audiodaten (DTv) ausführt, bevor während der Lese- und Adressensprungoperationen (J1) weitere Audiodatenlese- und Adressensprung-

operationen (J2) auf der Basis neuer Audiodaten (FFDT, FRDT) ausgeführt werden, und die Leseeinrichtung (3, 6) unabhängig Spursprungoperationen so ausführt, dass die bei der Spur vorhandenen Daten, zu welcher die Leseeinrichtung (3, 6) springt, aus dieser Spur ausgelesen werden, um in den Speicher (13) als die neuen Audiodaten (FFDT, FRDT) geschrieben zu werden.

10. Wiedergabeverfahren nach Anspruch 9, wobei

beim Eingestellt sein des Hochgeschwindigkeits-Wiedergabeoperationszustandes eine vorgewählte Menge der in der Speichereinrichtung (13) gespeicherten Audiodaten auf diskontinuierliche Weise aus derselben gelesen werden.

11. Wiedergabeverfahren nach Anspruch 10, wobei

beim Eingestellt sein des Hochgeschwindigkeits-Wiedergabeoperationszustandes die Leseeinrichtung (3) in Bezug auf das Aufzeichnungsmedium (1) derart relativ transportiert wird, dass die Audiodaten aus dem Aufzeichnungsmedium (1), dessen Datenmenge größer als eine solche Datenmenge der Audiodaten ist, gelesen werden, wenn die in der Speichereinrichtung (13) gespeicherten Audiodaten aus derselben gelesen werden.

12. Wiedergabeverfahren nach Anspruch 11, wobei

beim Eingestellt sein des Hochgeschwindigkeits-Wiedergabeoperationszustandes die Leseeinrichtung (3) in Bezug auf das Aufzeichnungsmedium (1) mit hoher Geschwindigkeit von einer Adresse derart, dass sie an den vorher in der Speichereinrichtung (13) gespeicherten Audiodaten fortgesetzt und zeitlich stromabwärts angeordnet ist, relativ transportiert wird, wobei die aus der Aufzeichnungseinrichtung gelesenen Audiodaten in die Speichereinrichtung geschrieben werden.

13. Wiedergabeverfahren nach einem der vorhergehenden Ansprüche, wobei

beim Schalten vom Hochgeschwindigkeits-Wiedergabeoperationszustand in einen normalen Wiedergabeoperationszustand die in der Speichereinrichtung (13) gespeicherten Audiodaten zu dem Zeitpunkt, bei dem der Hochgeschwindigkeits-Wiedergabeoperationszustand in den normalen Wiedergabeoperationszustand geschaltet wird, kontinuierlich gelesen werden.

14. Wiedergabeverfahren nach Anspruch 13, wobei

nach dem Bringen des Operationszustandes in den normalen Wiedergabeoperationszustand die aus dem Aufzeichnungsmedium (1) gelesenen Audiodaten in die Speichereinrichtung (13) von einer Kopfposition der eine von einer Adresse der aus der Speichereinrichtung (13) gelesenen Audiodaten verschiedene andere Adresse aufweisenden Audiodaten zu dem Zeitpunkt geschrieben werden, bei dem der Hochgeschwindigkeits-Wiedergabeoperationszustand in den normalen Wiedergabeoperationszustand geschaltet wird.

15. Wiedergabeverfahren nach Anspruch 14, wobei

eine Feststellung getroffen wird, ob die Adresse der zu dem Zeitpunkt aus der Speichereinrichtung (13) gelesenen Audiodaten, bei dem der Hochgeschwindigkeits-Wiedergabeoperationszustand in den normalen Wiedergabeoperationszustand wechselt, sich bei einer anderen Adresse, die um einen vorbestimmten Abstand von den beim Wechselzeitpunkt aus der Speichereinrichtung (13) gelesenen Audiodaten getrennt ist, fortgesetzt ist oder nicht, wobei eine Kopfposition der die andere Adresse aufweisenden Audiodaten bestimmt wird.

Revendications

1. Appareil de reproduction destiné à un support d'enregistrement, comprenant :

un moyen de lecture (3, 6) se déplaçant de façon relative par rapport à un support d'enregistrement (1), destiné à lire des données audio enregistrées sur le support d'enregistrement (1),

un moyen de mémoire (13) destiné à mémoriser temporairement dans celui-ci les données audio lues à partir du support d'enregistrement (1) par ledit moyen de lecture (3, 6), et

un moyen de commande (12) destiné à commander une opération d'écriture (DSC) desdites données audio dans ledit moyen de mémoire (13) et une opération de lecture (ASC) desdites données audio (DTV) mémorisées dans ledit moyen de mémoire (13), dans lequel ledit moyen de commande (12) commande en vue d'écrire les données audio dans ledit moyen de mémoire (13) et de lire les données audio à partir de celui-ci de manière telle qu'une vitesse d'écriture des données audio lues par ledit moyen de lecture (3, 6) devienne plus élevée qu'une vitesse de lecture des données audio

mémorisées dans ledit moyen de mémoire (13), dans lequel, lorsqu'une condition d'opération de reproduction à haute vitesse (FF, FR) est établie, ledit moyen de commande (12) provoque le transport relatif dudit moyen de lecture (3, 6) à haute vitesse par rapport au support d'enregistrement (1), d'où il résulte que le traitement de l'opération de reproduction à haute vitesse desdites données audio est exécuté, lesquelles sont lues à partir du support d'enregistrement (1) pour être écrites dans ledit moyen de mémoire,

caractérisé en ce que,

lorsqu'une condition d'opération de reproduction à haute vitesse (FF, FR) est établie, ledit moyen de commande (12) provoque en outre des opérations de saut à une adresse (J1) en vue de lire (ASC) la mémoire (13) en fonction des données audio mémorisées précédemment (DTv) pour l'opération de reproduction normale (PB) avant la lecture d'autres données audio et des opérations de saut d'adressage (J2) fondées sur de nouvelles données audio (FFDT, FRDT) soient exécutées durant lesdites opérations de lecture et de saut d'adressage (J1, J2), le moyen de lecture (3, 6) exécutant indépendamment les opérations de saut de piste, de sorte que les données présentes au niveau de la piste vers laquelle saute le moyen de lecture (3, 6) soient lues à partir de cette piste pour être écrites dans ladite mémoire (13) en tant que lesdites nouvelles données audio (FFDT, FRDT).

2. Appareil de reproduction destiné à un support d'enregistrement selon la revendication 1, dans lequel :

lorsque ladite condition d'opération de reproduction à haute vitesse est établie, ledit moyen de commande (12) provoque la lecture d'une quantité présélectionnée desdites données audio mémorisées dans ledit moyen de mémoire (13) à partir de celle-ci de manière discontinue.

3. Appareil de reproduction destiné à un support d'enregistrement selon la revendication 2, dans lequel :

lorsque ladite condition d'opération de reproduction à haute vitesse est établie, ledit moyen de commande (12) provoque le transport relatif dudit moyen de lecture (3) par rapport au support d'enregistrement (1) de telle manière que lesdites données audio soient lues à partir du support d'enregistrement, dont la quantité de données est plus grande qu'une telle quantité de données des données audio lorsque lesdites données audio mémorisées dans ledit moyen de mémoire sont lues à partir de celui-ci.

4. Appareil de reproduction destiné à un support d'enregistrement selon la revendication 3, dans lequel :

lorsque ladite condition d'opération de reproduction à haute vitesse est établie, ledit moyen de commande (12) provoque le transport relatif dudit moyen de lecture à haute vitesse par rapport au support d'enregistrement à partir d'une adresse telle qu'elle suit les données audio mémorisées précédemment dans ledit moyen de mémoire (13) et est située temporairement en aval, d'où il résulte que les données audio lues à partir du support d'enregistrement sont écrites dans ledit moyen de mémoire.

5. Appareil de reproduction destiné à un support d'enregistrement selon l'une quelconque des revendications précédentes, dans lequel :

lorsqu'il y a passage de ladite condition d'opération de reproduction à haute vitesse vers une condition d'opération de reproduction normale, ledit moyen de commande provoque la lecture continue des données audio mémorisées dans ledit moyen de mémoire (12) à l'instant auquel ladite condition d'opération de reproduction à haute vitesse passe dans la condition d'opération de reproduction normale.

6. Appareil de reproduction destiné à un support d'enregistrement selon la revendication 5, dans lequel :

après que la condition de l'opération a été amenée dans ladite condition d'opération de reproduction normale, ledit moyen de commande (12) provoque l'écriture des données audio lues à partir dudit support d'enregistrement (1) dans ledit moyen de mémoire (13) à partir d'une position de tête des données audio ayant une adresse différente d'une adresse des données audio lues à partir dudit moyen de mémoire (13) à l'instant auquel ladite condition d'opération de reproduction à haute vitesse est passée dans ladite condition d'opération de reproduction normale.

7. Appareil de reproduction destiné à un support d'enregistrement selon la revendication 6, dans lequel :

ledit moyen de commande (12) évalue si l'adresse des données audio lues à partir dudit moyen de mémoire (13) à l'instant auquel ladite condition d'opération de reproduction à haute vitesse est passée dans la condition d'opération de reproduction normale est à la suite ou non d'une adresse des données audio séparées d'une distance prédéterminée desdites données audio lues à partir du moyen de mé-

moire audit instant de changement, d'où il résulte qu'une position de tête des données audio ayant ladite adresse différente est déterminée.

8. Appareil de reproduction destiné à un support d'enregistrement selon la revendication 6, dans lequel :

ledit moyen de commande (12) compare l'adresse des données audio lues à partir dudit moyen de mémoire (13) à l'instant auquel ladite condition d'opération de reproduction à haute vitesse est passée en ladite condition d'opération de reproduction normale avec une adresse des données audio séparées d'une distance prédéterminée des données audio lues à partir dudit moyen de mémoire (13) audit instant de changement, et lorsqu'un résultat de comparaison implique que l'adresse desdites données audio lues n'est pas à la suite de l'adresse desdites données audio séparées de ladite distance prédéterminée par rapport à celle-ci, ledit moyen de commande (12) écrit les données audio lues à partir dudit moyen de lecture depuis lesdites données audio séparées à une position de tête.

9. Procédé destiné à reproduire un support d'enregistrement (1) dans lequel des données audio sont enregistrées en même temps que des données d'adressage sur un support d'enregistrement (1), les données audio lues à partir dudit support d'enregistrement par un moyen de lecture (3, 6) sont mémorisées une première fois dans un moyen de mémoire (13), les données audio mémorisées dans le moyen de mémoire (13) sont lues, et les données audio sont écrites/lues dans/depuis le moyen de mémoire (13) de manière telle qu'une vitesse d'écriture des données audio lues à partir du support d'enregistrement (1) est plus élevée qu'une vitesse de lecture des données audio mémorisées dans le moyen de mémoire (13), dans lequel, lorsqu'une condition d'opération de reproduction à haute vitesse est établie, ledit moyen de lecture (3, 6) est transporté de façon relative à une vitesse élevée par rapport au support d'enregistrement (1), d'où il résulte que le traitement d'opération de reproduction à haute vitesse desdites données audio est exécuté, lesquelles sont lues à partir du support d'enregistrement (1) pour être écrites dans ledit moyen de mémoire, **caractérisé en ce que** dans lequel lorsqu'une condition d'opération de reproduction à haute vitesse est établie, ledit procédé de reproduction exécute en outre des opérations de saut d'adressage (J1) afin de lire (ASC) la mémoire (13) en fonction des données audio mémorisées précédemment (DTv) pour l'opération de reproduction normale (PB) avant la lecture d'autres données

audio et des opérations de saut d'adressage (J2) fondées sur de nouvelles données audio (FFDT, FRDT) soient exécutées durant lesdites opérations de lecture et de saut d'adressage (J1, J2), le moyen de lecture (3, 6) exécutant indépendamment des opérations de saut de piste, de sorte que les données présentes au niveau de la piste vers laquelle saute le moyen de lecture (3, 6) sont lues à partir de cette piste pour être écrites dans ladite mémoire (13) en tant que lesdites nouvelles données audio (FFDT, FRDT).

10. Procédé de reproduction selon la revendication 9, dans lequel :

lorsque ladite condition d'opération de reproduction à haute vitesse est établie, une quantité présélectionnée desdites données audio mémorisées dans ledit moyen de mémoire (13) est lue à partir de celui-ci de manière discontinue.

11. Procédé de reproduction selon la revendication 10, dans lequel :

lorsque ladite condition d'opération de reproduction à haute vitesse est établie, ledit moyen de lecture (3) est transporté de façon relative par rapport au support d'enregistrement (1) de telle manière que lesdites données audio soient lues à partir du support d'enregistrement (1), dont la quantité de données est plus grande qu'une telle quantité de données des données audio lorsque lesdites données audio mémorisées dans ledit moyen de mémoire (13) sont lues à partir de celui-ci.

12. Procédé de reproduction selon la revendication 11, dans lequel :

lorsque ladite condition d'opération de reproduction à haute vitesse est établie, ledit moyen de lecture (3) est transporté de façon relative à haute vitesse par rapport au support d'enregistrement (1) à partir d'une adresse telle qu'elle est à la suite des données audio mémorisées précédemment dans ledit moyen de mémoire (13) et est située temporairement en aval, d'où il résulte que les données audio lues à partir du moyen d'enregistrement sont écrites dans ledit moyen de mémoire (13).

13. Procédé de reproduction selon l'une quelconque des revendications 9 à 12, dans lequel :

lorsque ladite condition d'opération de reproduction à haute vitesse est basculée en une condition d'opération de reproduction normale,

les données audio mémorisées dans ledit moyen de mémoire (13) à l'instant où ladite condition d'opération de reproduction à haute vitesse est basculée en la condition d'opération de reproduction normale, sont lues de façon continue.

5

14. Procédé de reproduction selon la revendication 13, dans lequel :

10

après que la condition d'opération a été amenée dans ladite condition d'opération de reproduction normale, les données audio lues à partir dudit support d'enregistrement (1) sont écrites dans ledit moyen de mémoire (13) à partir d'une position de tête des données audio présentant une adresse différente d'une adresse des données audio lues à partir dudit moyen de mémoire (13) à l'instant où ladite condition d'opération de reproduction à haute vitesse est basculée en ladite condition d'opération de reproduction normale.

15

20

15. Procédé de reproduction selon l'une quelconque des revendications 9 à 14, dans lequel :

25

une évaluation est faite de ce que l'adresse des données audio lues à partir dudit moyen de mémoire (13) à l'instant où ladite condition d'opération de reproduction à haute vitesse est changée en la condition d'opération de reproduction normale est à la suite ou non d'une adresse des données audio séparées d'une distance prédéterminée par rapport aux données audio lues depuis le moyen de mémoire (13) audit instant de changement, d'où il résulte qu'une position de tête des données audio présentant ladite adresse différente est déterminée.
